## Intel Labs Haskell Research Compiler

Hai (Paul) Liu
with Neal Glew, Leaf Peterson, Todd A. Anderson Intel Labs. September 28, 2016

## Intel Labs Haskell Research Compiler

An alternative Haskell compiler that:

- uses GHC as frontend;
- does whole program compilation;

## Intel Labs Haskell Research Compiler

An alternative Haskell compiler that:

- uses GHC as frontend;
- does whole program compilation;
- achieves overall performance parity with GHC+LLVM;
- is significantly better for some programs;

## Intel Labs Haskell Research Compiler

An alternative Haskell compiler that:

- uses GHC as frontend;
- does whole program compilation;
- achieves overall performance parity with GHC+LLVM;
- is significantly better for some programs;
- does automatic SIMD vectorization for Intel CPUs.

## However...

The backend of HRC was not originally designed for Haskell.

## However...

The backend of HRC was not originally designed for Haskell.
We re-purposed an existing FL compiler and runtime that:

- has a set of different design decisions;
- makes an interesting comparison to GHC.

## However...

The backend of HRC was not originally designed for Haskell.
We re-purposed an existing FL compiler and runtime that:

- has a set of different design decisions;
- makes an interesting comparison to GHC.

Known Limitations:

- No lightweight threads, sparks, or STM (easy);
- No exception re-throw for thunks (fixable);
- No asynchronous exceptions (hard).

## Functionality

HRC is highly compatible to GHC:

- Modified GHC and base libraries to handle differences;
- Modified Vector library to use initializing writes;
- Modified Cabal to compile for HRC;
- Little or no modifications to most other libraries.

## Compilation Process

## Inside HRC Pipeline

## Comparison to GHC

| GHC |  | HRC |  |
| :---: | :--- | :---: | :--- |
| Desugaring <br> Type analysis <br> Core-to-Core transformation |  |  |  |
| STG | Functional, object memory model, <br> optimized for currying and thunks | MIL | CFG/SSA based, object <br> memory model, conventional |
| Cmm | CFG blocks, low-level types, <br> and custom calling convention | Pillar | C types, C calling convention <br> meta and GC support |
| LLVM or <br> NCG | Portable LLVM bitcode, or <br> direct assembly generation | Intel C/C++ <br> Compiler | Portable C code <br> compiled to assembly |
| Runtime <br> and GC | Optimized for currying and thunks | Runtime <br> and GC | Conventional |

- High level object model with low level control flow
- Leveraging immutability and memory safety
- Data flow and control flow analysis
- Inter- and intra- procedural optimizations
- Representation/contification/loop/thunk optimizations
- SIMD auto vectorization

## Immutable Array

GHC creates an immutable array by:

- creating a mutable array;
- writing to it;
- freezing the result.

## Immutable Array

GHC creates an immutable array by:

- creating a mutable array;
- writing to it;
- freezing the result.

HRC separates array creation and initialization, with primitives to:

- create immutable array
- do initializing writes
- read

## Immutable Array

GHC creates an immutable array by:

- creating a mutable array;
- writing to it;
- freezing the result.

HRC separates array creation and initialization, with primitives to:

- create immutable array
- do initializing writes
- read

Programmers must ensure:

- an array field is written to before it is read;
- a field is never written to more than once.

## Walkthrough by Example

odd, even $::$ Int $\rightarrow$ Bool<br>odd $0=$ False<br>odd $n=\operatorname{even}(n-1)$<br>even $0=$ True<br>even $n=$ odd $(n-1)$

## GHC Core

    L4(): Return(gv_False)
    L5(): Return(gv_True)
    }
```

## Benchmarking

40+ benchmark programs:

- a mixed set of programs from nofib benchmark suite;
- performance oriented programs using array libraries.

Sequential performance is measured by compiling and running on 2.7 GHz Xeon machine (32-bit Windows) with:

- standard GHC 7.6.1
- GHC 7.6.1 + LLVM 2.9
- HRC with modified GHC 7.6.1 + Intel C/C++ compiler.

## Benchmark Result

HRC is at parity to GHC+LLVM, which is $10 \%$ faster than GHC.

Figure: Kernel Execution Time Relative to GHC (smaller is better)

## Benchmark Result (selected)

Performance oriented program with a numeric computation kernel using arrays.

Figure: Kernel Execution Time Relative to GHC (smaller is better)

## Performance

For GHC:

- GHC is better at executing lazy code and curried functions.
- GHC's object representation and GC are better suited to typical Haskell programs.

## For HRC:

- HRC focuses on optimizing strict programs with hot loops.
- HRC benefits significantly from the elimination of thunks, boxes and branches.

## Take Aways

- Reusing GHC is a big win (Core: easy, library: a bit work)
- Novel MIL design choices:
- Low-level control with high-level object.
- Immutable array with initializing writes.
- Eliminating thunks is critical to performance.
- Penalty of not using a specialized runtime.
- Compilation through $C$ has overhead, but not as significant.
